

ON-CHAIN CHEAT SHEET · V1

The 8 Kasper numbers that actually matter. And how to read them.

A one-page-per-number guide to the on-chain signals that tell you what's really happening under the KAS chart. Every number here is public, checkable in 30 seconds, and updated weekly on kaspapulse.com.

INSIDE

1 · Total DeFi TVL	capital committed on-chain
2 · DEX volume (24h)	real trading activity
3 · Unique active addresses	daily usage, honestly counted
4 · Covenant transactions	smart-contract adoption
5 · Addresses holding KAS	reach, not people
6 · KAS on exchanges	the sell-side supply
7 · Supply untouched 1y+	real conviction
8 · Entity X balance	the biggest wallet on the chain

not financial advice · verify anything yourself, links inside

NUMBER 01 · TOTAL DEFI TVL

How much capital is actually committed to Kaspas DeFi.

See today's number live · both L2s added up

[KASPAPULSE.COM](https://kaspapulse.com) →

— What it is

Total Value Locked adds up every dollar currently sitting in Kaspas DeFi protocols across both Layer-2s, **Kasplex** and **Igra**. Think of it as capital that people have parked in the ecosystem instead of holding KAS in their wallet. Kaspas L1 itself has no TVL yet, only the L2s do the DeFi part.

For context

Ethereum needed years after launch before its DeFi TVL first crossed \$1 billion, and it took until 2020 for DeFi to become a real category at all. Kaspas DeFi is **weeks to months old**. Absolute size doesn't matter yet, direction does.

— Where to check

DefiLlama chain pages, aggregated live: defillama.com/chain/kasplex and defillama.com/chain/igra. Most dashboards only show one chain. Adding both up is the honest headline.

— How to read it

SIGNAL TO WATCH

Direction matters more than size right now. Kaspas DeFi is still small in absolute terms, months old, so treat the trend as the signal. A steady weekly climb means builders are staying and users are trusting the rails. A sudden drop without an obvious cause (exploit, unwind) means capital is leaving faster than it comes in, that's the early warning.

NUMBER 02 · DEX VOLUME (24H)

How much KAS and KRC-20s actually change hands each day.

[See today's number live · all Kasper DEXs](#)[KASPAPULSE.COM](https://kaspapulse.com) →

— What it is

Trading volume on decentralized exchanges across both L2s per day. This is the number that tells you whether people actually trade Kasper tokens on Kasper, or whether they only trade KAS itself on centralized exchanges like Binance. The bigger this gets, the more the on-chain economy is alive.

For context

For every dollar of KAS traded on Kasper DEXs, many multiples of that trade on centralized exchanges like Binance. That gap is normal for young chains. The signal to watch is whether the gap **slowly closes over quarters**, that's the sign a native economy is forming.

— Where to check

DefiLlama's DEX dashboards per chain: defillama.com/dexs/chain/kasplex . For the honest total, both chains added.

— How to read it

SIGNAL TO WATCH

DEX volume rising while TVL stays flat means real trading, not fake liquidity. DEX volume rising alongside TVL means the ecosystem is maturing. Volume dropping while TVL stays high often signals speculators leaving, real users staying, that's not always bearish.

NUMBER 03 · UNIQUE ACTIVE ADDRESSES / DAY

How many wallets actually transact on any given day.

See today's number live · daily unique addresses

[KASPAPULSE.COM](https://kaspapulse.com) →

— What it is

The number of unique addresses that either sent or received KAS on a given day. This is the honest, deduplicated version, some dashboards show much bigger inflated numbers by counting every interaction.

For context

Bitcoin runs on roughly **600,000 to 1 million** daily active addresses, Ethereum has run in a similar range for years.

Kaspa's number reflects a chain still in the earliest phase of adoption. Comparison across chains isn't perfectly apples-to-apples, but the **growth rate** is.

— Where to check

Kaspalytics, chart "Number of Unique Active Addresses": kaspalytics.com

— How to read it

SIGNAL TO WATCH

Not every address is a person, some users have many. Look at the trend, not the absolute. A slow steady climb while price sleeps is one of the healthiest signals a chain can print, it means adoption is happening under the surface. A sudden spike usually means an airdrop, a hype cycle, or bot activity, treat with caution.

NUMBER 04 · COVENANT TRANSACTIONS / DAY

How much smart-contract activity actually runs on Kaspas L1.

[See today's number live · covenant activity](#)[KASPAPULSE.COM](https://kaspapulse.com) →

— What it is

Covenants are the Toccata-upgrade feature that lets Kaspas run programmable spending rules natively on L1, without a rollup. This number counts transactions that use them, an early proxy for smart-contract adoption on the base layer.

For context

Ethereum was the first chain to make smart contracts work at scale, everything since has been catching up in its own way. Kaspas approach is different: **programmable spending rules directly on Layer-1**, no rollup required. This metric measures how much of that potential is actually being used.

— Where to check

Kaspalytics Transaction Inspection, "Covenant-Creating Transactions": kaspalytics.com

— How to read it

SIGNAL TO WATCH

Went from zero to hundreds a day within weeks of Toccata. The first consumer apps using covenants started launching in mid-2026. If this number grows, it means Kaspas is becoming programmable at the base layer, not just via L2s. If it stalls, adoption is stuck at "cool primitive, nothing built on it yet."

NUMBER 05 · ADDRESSES HOLDING KAS

How many wallets hold at least a meaningful amount of KAS.

See today's number live · addresses ≥ 0.01 KAS

[KASPAPULSE.COM](https://kaspapulse.com) →

— What it is

Distinct on-chain addresses with at least a meaningful KAS balance (we use 0.01 KAS as the threshold). This filter matters, because Kaspa has tens of millions of "dust addresses" that hold near-zero amounts and would inflate any raw holder count. This is the honest number of real wallets.

For context

Address counts across chains aren't directly comparable, one person can hold ten wallets, one exchange can appear as one address, and each chain measures differently. What **is** comparable is the trend: healthy chains grow their meaningful-holder count year over year, especially through drawdowns.

— Where to check

Kaspalytics Supply → Distribution Table, sum all buckets ≥ 0.01 KAS: kaspalytics.com

— How to read it

SIGNAL TO WATCH

Addresses $\neq$ people. One person can hold many wallets. That said, this number grew steadily through the last drawdown even as price kept falling. Growth through a drawdown means new capital arrived quietly at cheaper prices. Watch the trend line, not the absolute number. A flat or declining line while price rises is a warning, that would be distribution.

NUMBER 06 · KAS ON EXCHANGES

How much KAS is sitting where it can be sold.

[See today's number live · exchange holdings](#)[KASPAPULSE.COM](https://kaspapulse.com) →

— What it is

KAS held on wallets labeled as exchange hot wallets (Binance, Gate, Bybit, Bitget and others). Coins sitting on an exchange are potential sell-side supply, they can hit the order book at any moment. Coins in self-custody usually can't.

For context

Bitcoin currently sits around **15 to 17 percent** of supply on exchanges and has trended down over the last few years, that's generally read as a constructive backdrop. Above 25 percent starts to look like distribution risk. Every chain runs at a different baseline, so **trend within a chain** matters more than the absolute level.

— Where to check

Kaspalytics Supply → Exchange Holdings: kaspalytics.com

— How to read it

SIGNAL TO WATCH

Direction is the whole signal here, invert the usual reading. Balances rising = coins moving toward sale = bearish pressure. Balances falling = coins leaving to self-custody = accumulation. A sustained multi-week decline is the flip signal to watch. Sustained decline while price stays flat is usually one of the earliest bullish structural signals.

NUMBER 07 · SUPPLY UNTOUCHED 1Y+

What share of all KAS hasn't moved in over a year.

[See today's number live · long-inactive share](#)[KASPAPULSE.COM](https://kaspapulse.com) →

— What it is

Share of circulating KAS that sat still for at least 365 days. These are coins in wallets that ignored every rally, every crash, every reason to sell. The closest thing to real conviction that on-chain data can measure.

For context

Bitcoin typically sits around **60 to 70 percent** long-inactive, Ethereum has run in a similar range in recent years. Anything above 50 percent is considered strong across major chains, and it usually takes years of holder maturation to get there.

— Where to check

Kaspalytics Supply → Inactive Supply → "Inactive for 1+ Year": kaspalytics.com

— How to read it

SIGNAL TO WATCH

Rising steadily = holders sitting through pain, that's structural. Sudden drop = old wallets waking up, which almost always precedes selling (some analysts call this "coin days destroyed"). When this share sits high and keeps climbing through a bear market, that's one of the strongest structural signals a chain can print, most chains dream of this level of long-term conviction.

NUMBER 08 · ENTITY X BALANCE

The biggest single wallet on Kaspas, and what it's doing.

[See today's balance](#) live · entity x wallet[KASPAPULSE.COM/ENTITY-X](https://kaspapulse.com/entity-x) →

— What it is

The single largest Kaspas address on the entire chain. Block explorers label it "Entity X", nobody knows who controls it. What makes it interesting isn't just the size, it's the pattern, steady weekly withdrawals from exchanges into cold storage, and never a single coin sent back the other way.

For context

Bitcoin's largest single address holds around **1 percent** of supply (an exchange cold wallet). Satoshi Nakamoto's estimated stash across many addresses is roughly **5 percent**. Ethereum's largest addresses are mostly exchange custody, so aren't a fair single-owner comparison. Kaspas's largest wallet is meaningful but **not without precedent**.

— Where to check

Explorer: [kaspas.stream](#), ranked #1 in the rich list and labeled "Entity X". Live balance and full context:

kaspapulse.com/entity-x.html

— How to read it

SIGNAL TO WATCH

The day this wallet moves toward an exchange, everything about the read changes. Until then, the pattern is one of the loudest single-address accumulation signals in crypto right now. Two things to hold in mind at the same time: **concentration is a real risk** (one unknown party controls a meaningful share of supply), and **direction is the story** (they keep buying, never selling). Track it weekly, not daily.

That's the sheet. **Now the important part.**

Numbers move every week. This cheat sheet is a snapshot, useful as a decoder ring, but the value is watching how each metric changes over time.

That's what we do at Kaspapulse. Every Monday, one email: fresh numbers, one line of context per section, a short "the read" that tells you what actually changed. **No hype, no price targets, no shilling.**

Get these 8 numbers, every Monday.

GROUND RULES

- **Verify everything yourself.** Every source is public and linked. Don't trust our numbers, check them.
- **One data point is noise, a trend is a signal.** Look at direction over 4–8 weeks, not day to day.
- **On-chain doesn't predict the price.** It shows what holders and users are doing. Draw your own conclusions.
